

# Understanding pattern & change in the Arctic: can we get there from here?

Russell Hopcroft,  
Ksenia Kosobokova

2000  $\mu\text{m}$

# *The Problem*

- Increasing desire to know the “status” of the Arctic: IF it is changing, WHAT will it look like in the future
- There are two fundamental requirements for this:
  1. we know/understand baseline patterns
  2. we need consistent time-series observations

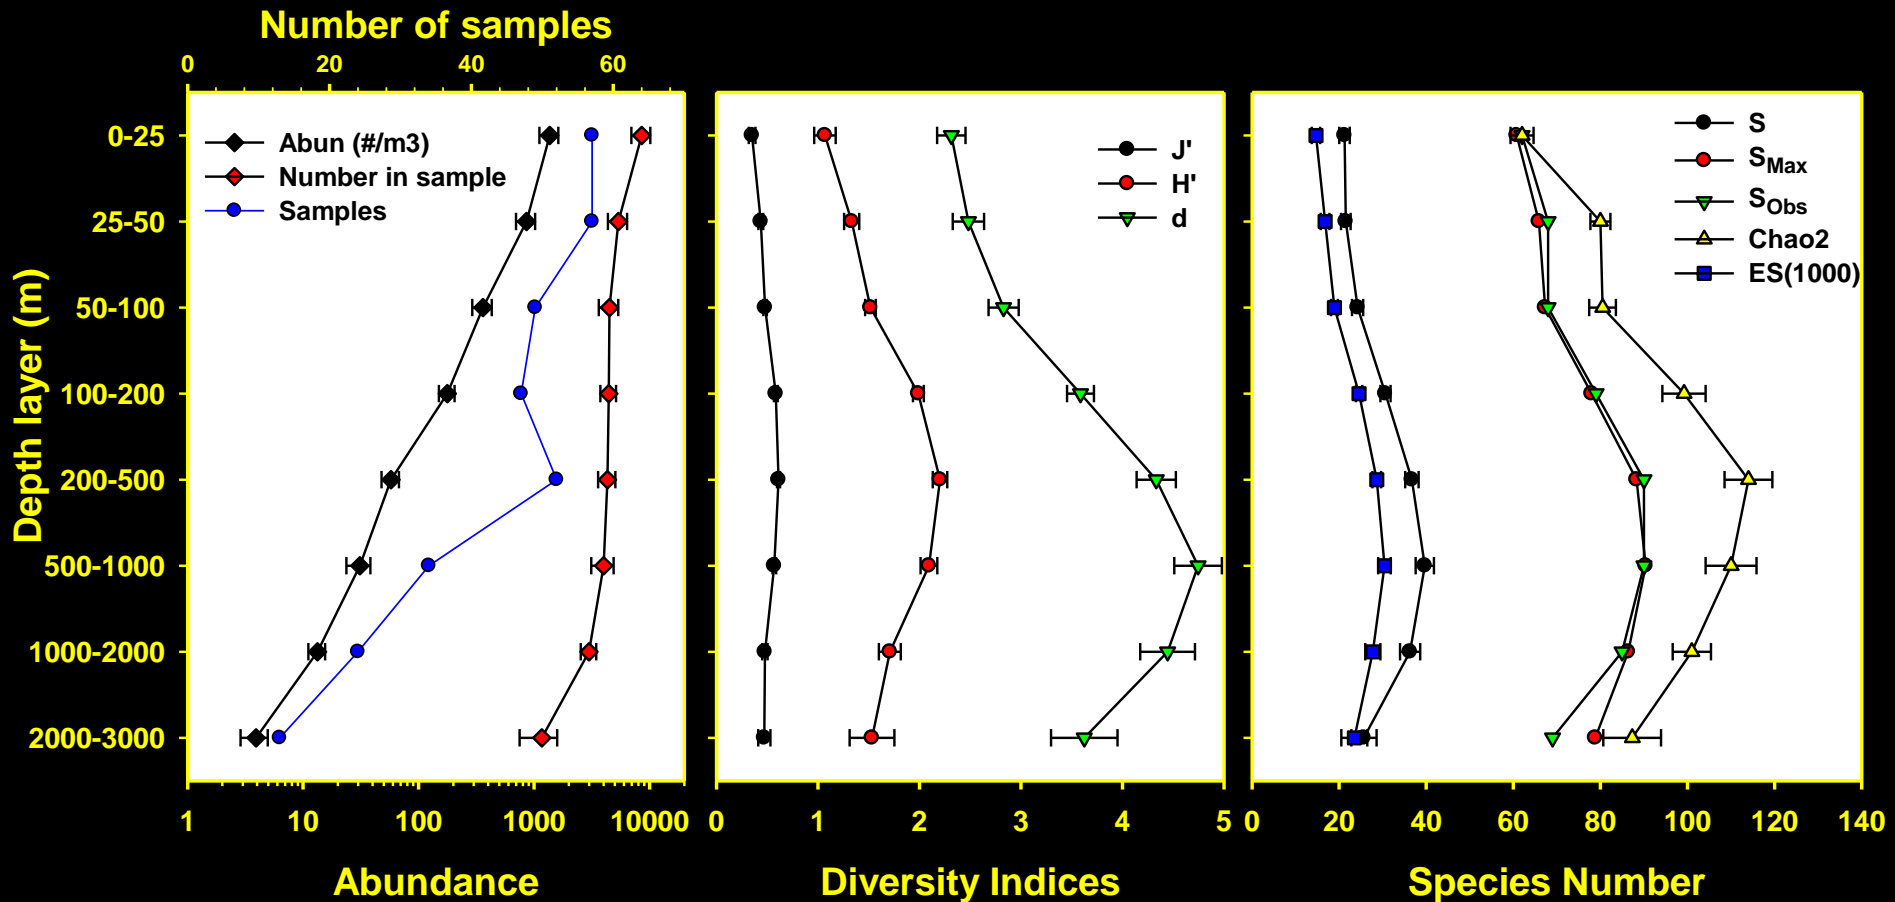

**Data  
consolidation**

**CoML  
CBMP**

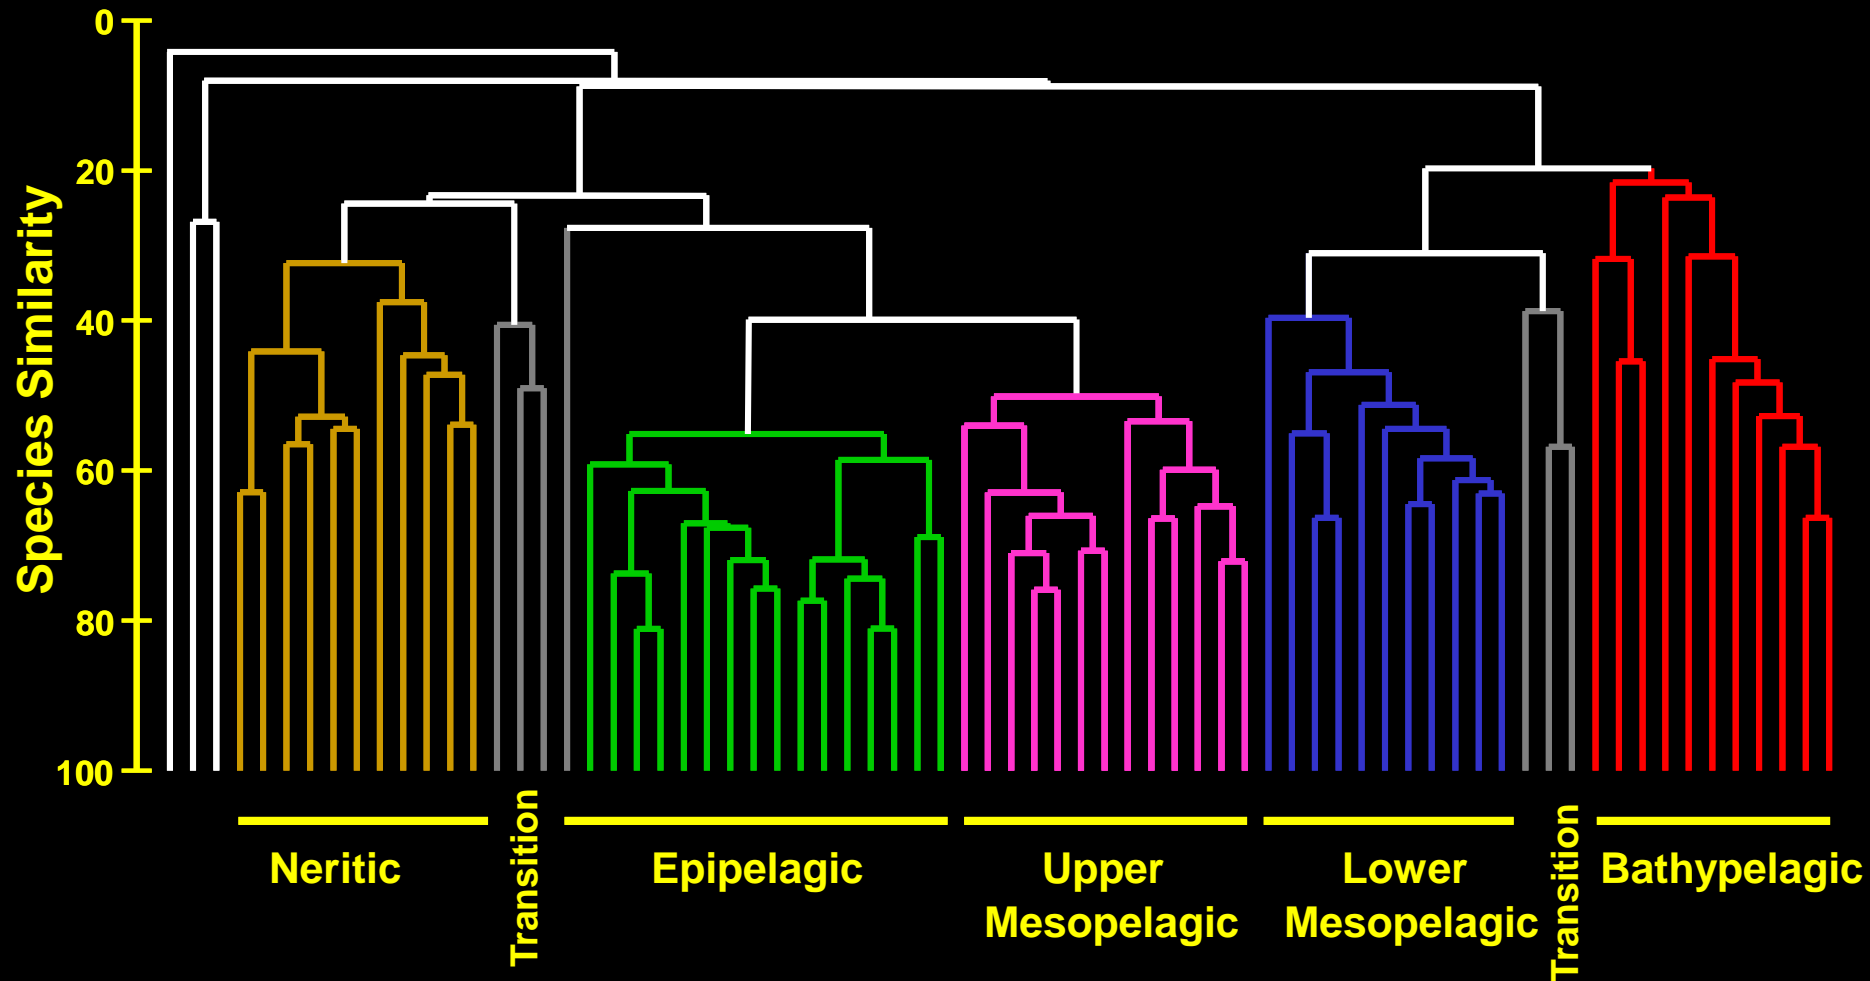

**Caveat: that  
Greatest  
biodiversity  
data density  
in Pacific-  
Arctic**

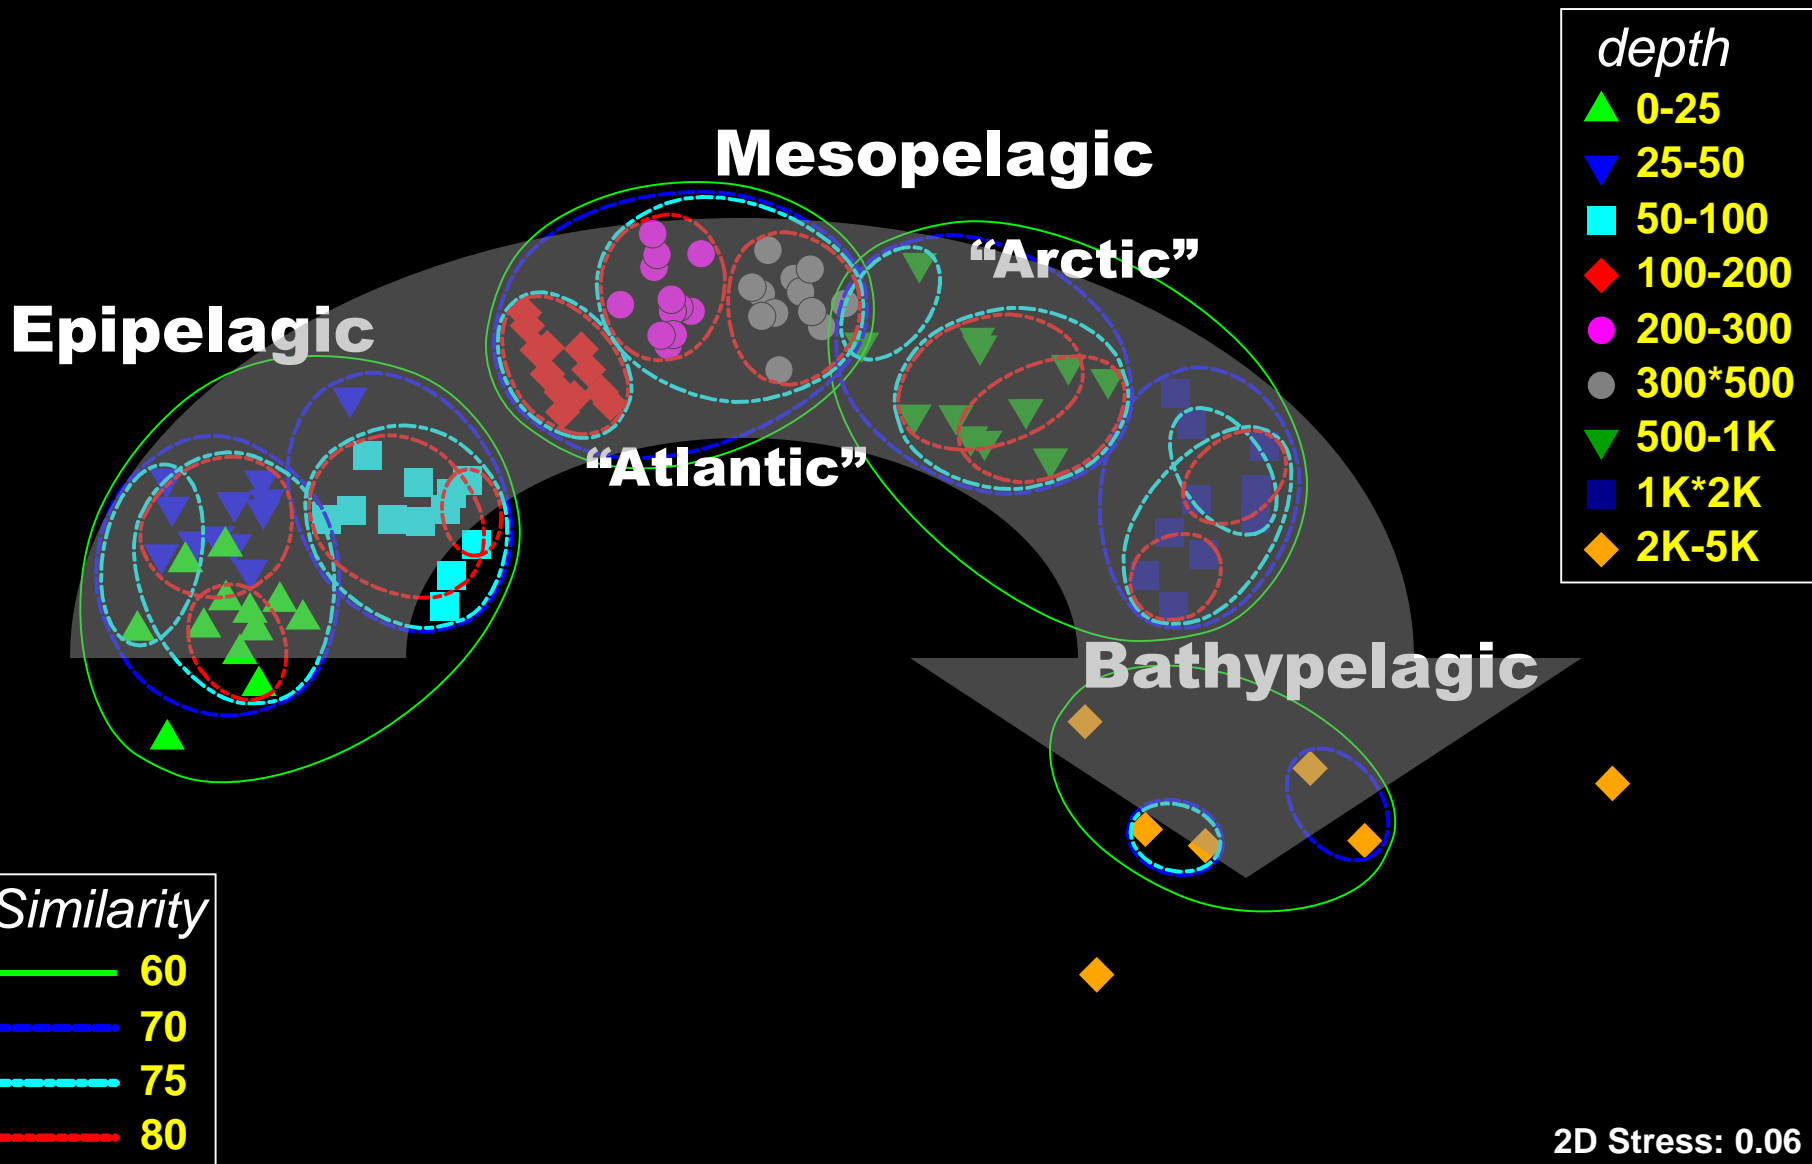

# Through CoML, we now understand biodiversity in the basins *based on consistent methods*

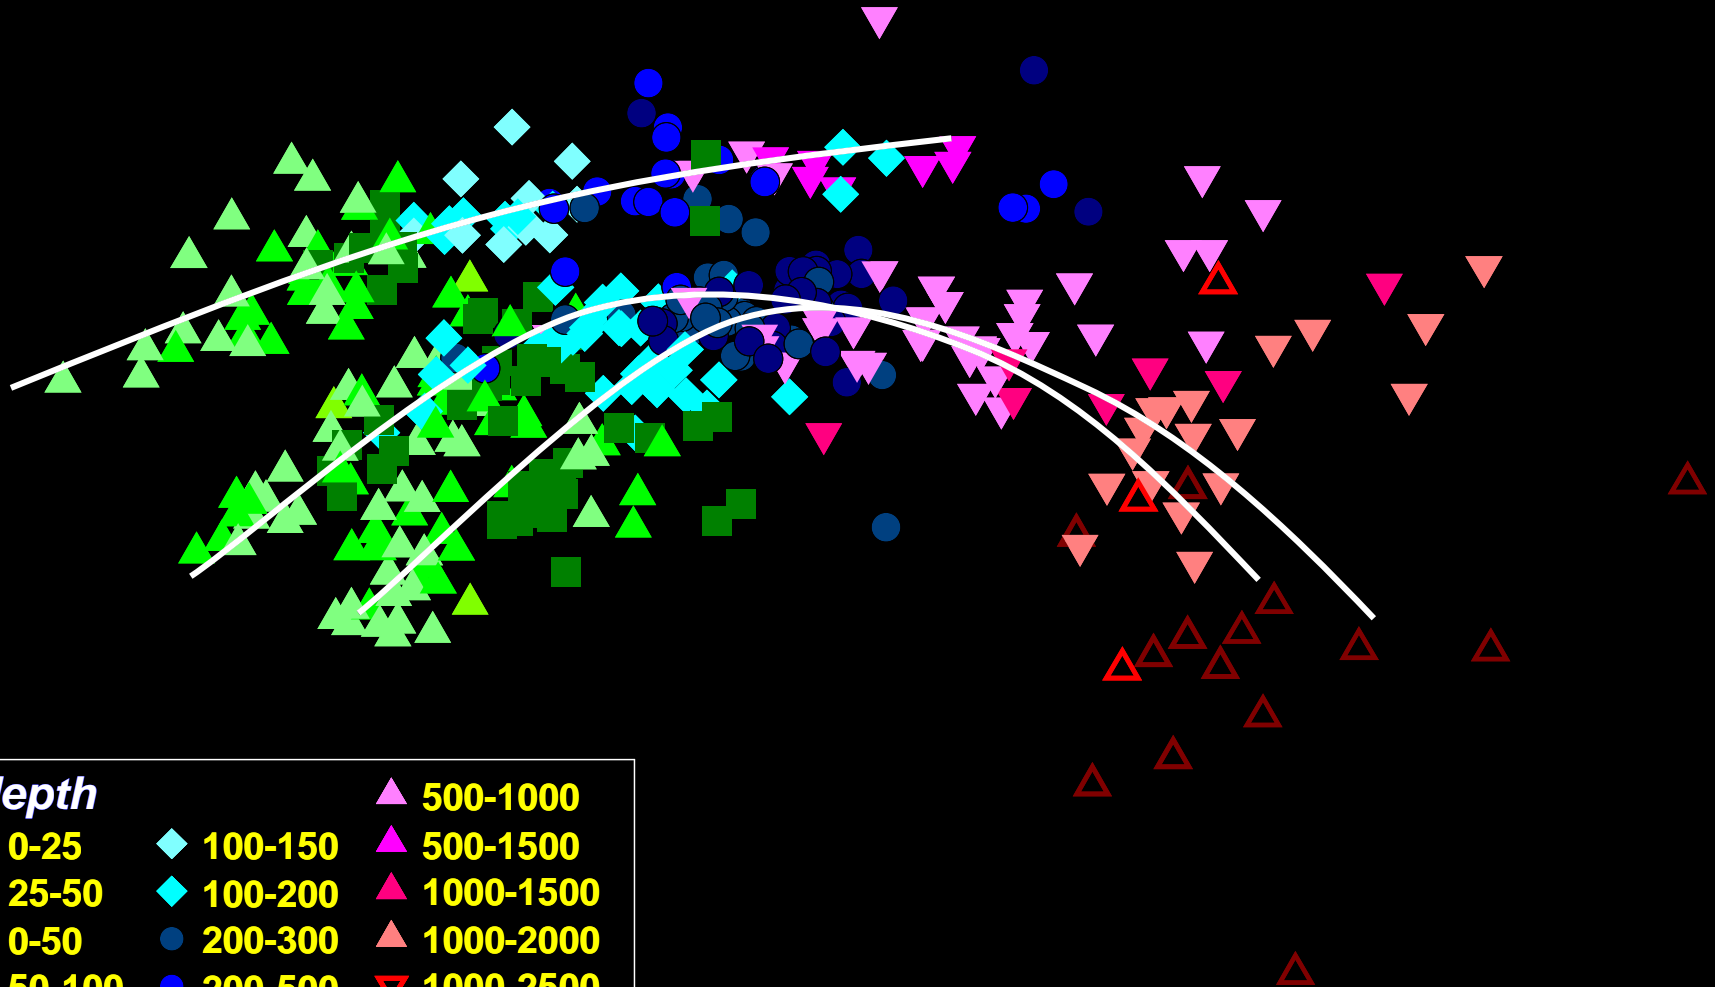

# Community patterns: hierarchical clustering of Bray-Curtis Similarity coefficient

# Multidimensional Scaling Projection

# Patterns hold for entire Arctic with some regional variation

## depth

(e.g. from 3 cruises)

2D Stress: 0.12

Basin communities are distinctive, but can we make progress on Arctic Shelves where interannual variability is high?

2000  $\mu\text{m}$

# Chukchi & Beaufort Shelves

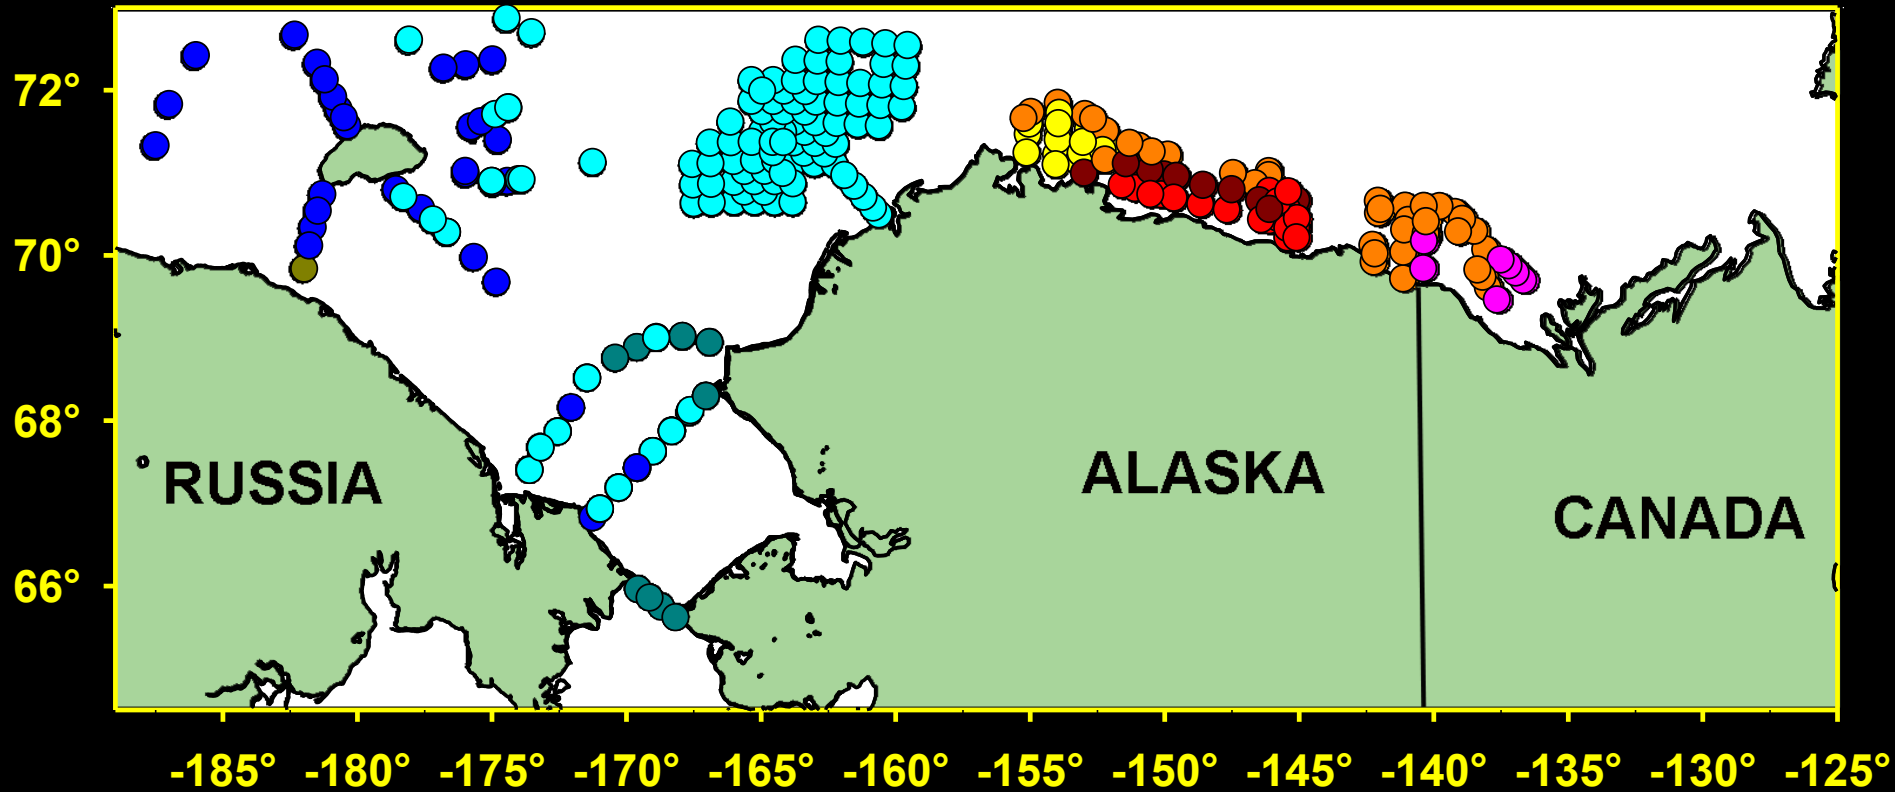

- Sampling from 2004-2014, ~Aug-Sept
- Consistent collection (vertical 150 $\mu$ m nets) with integration to bottom (or 200m)
- Consistent processing
- ~700 samples available for analysis (subset used)
- Community structure analyzed using Bray-Curtis similarity, subjected to Clustering and nMDS

# A structured mess

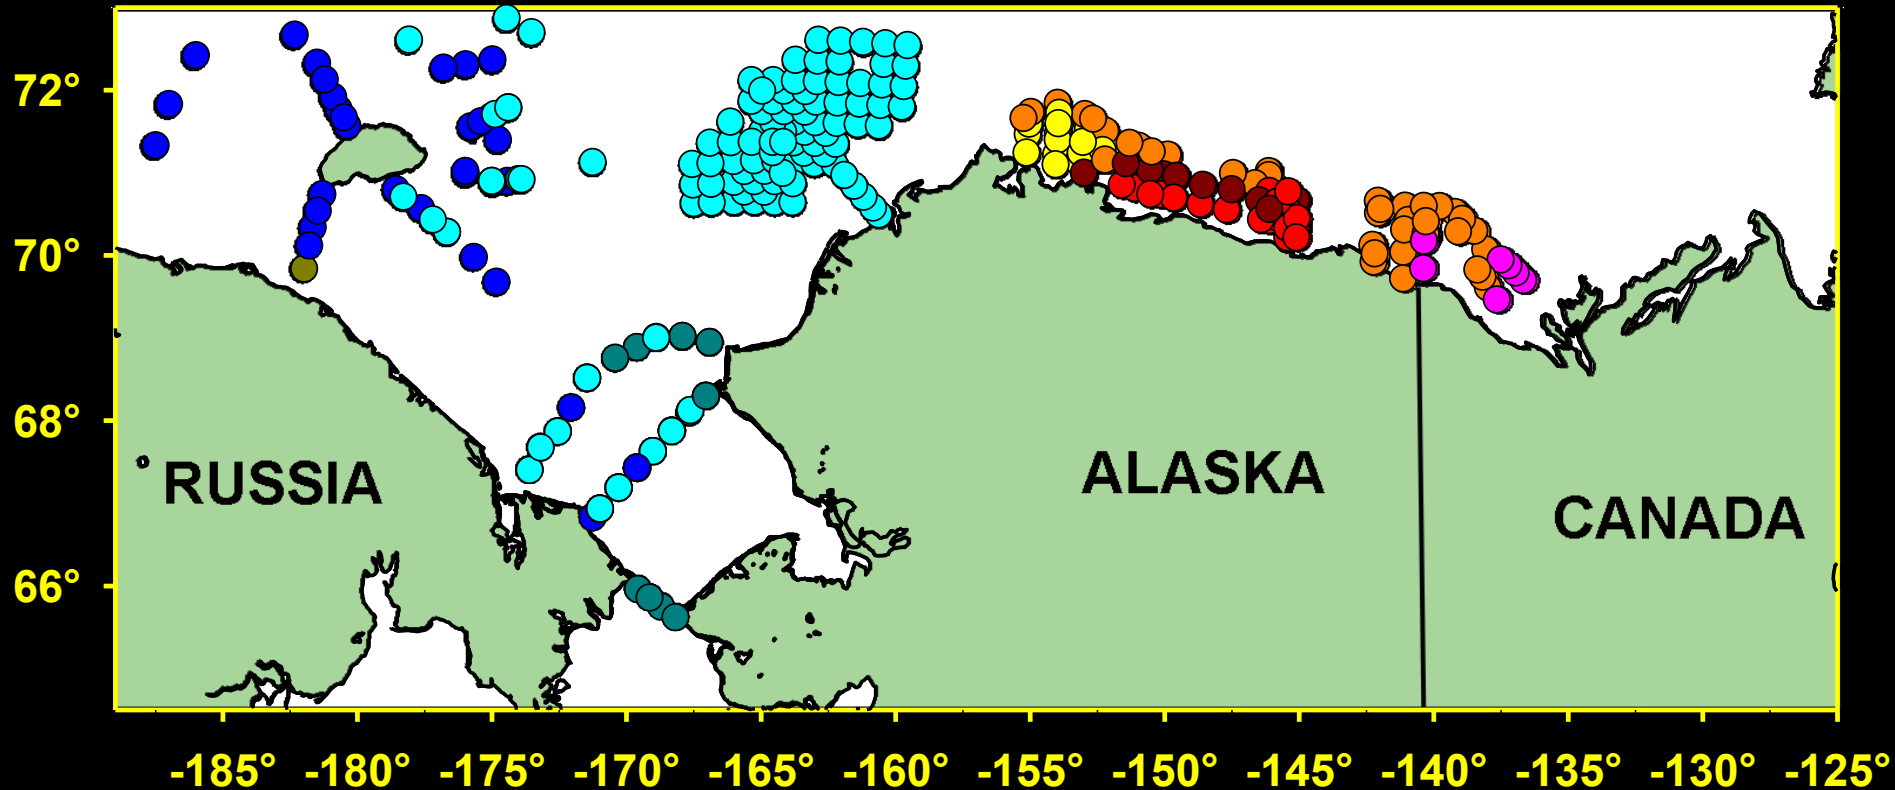

# Chukchi & Beaufort Shelves

- Chukchi and Beaufort are distinct
- East Siberian is more like Chukchi than Beaufort

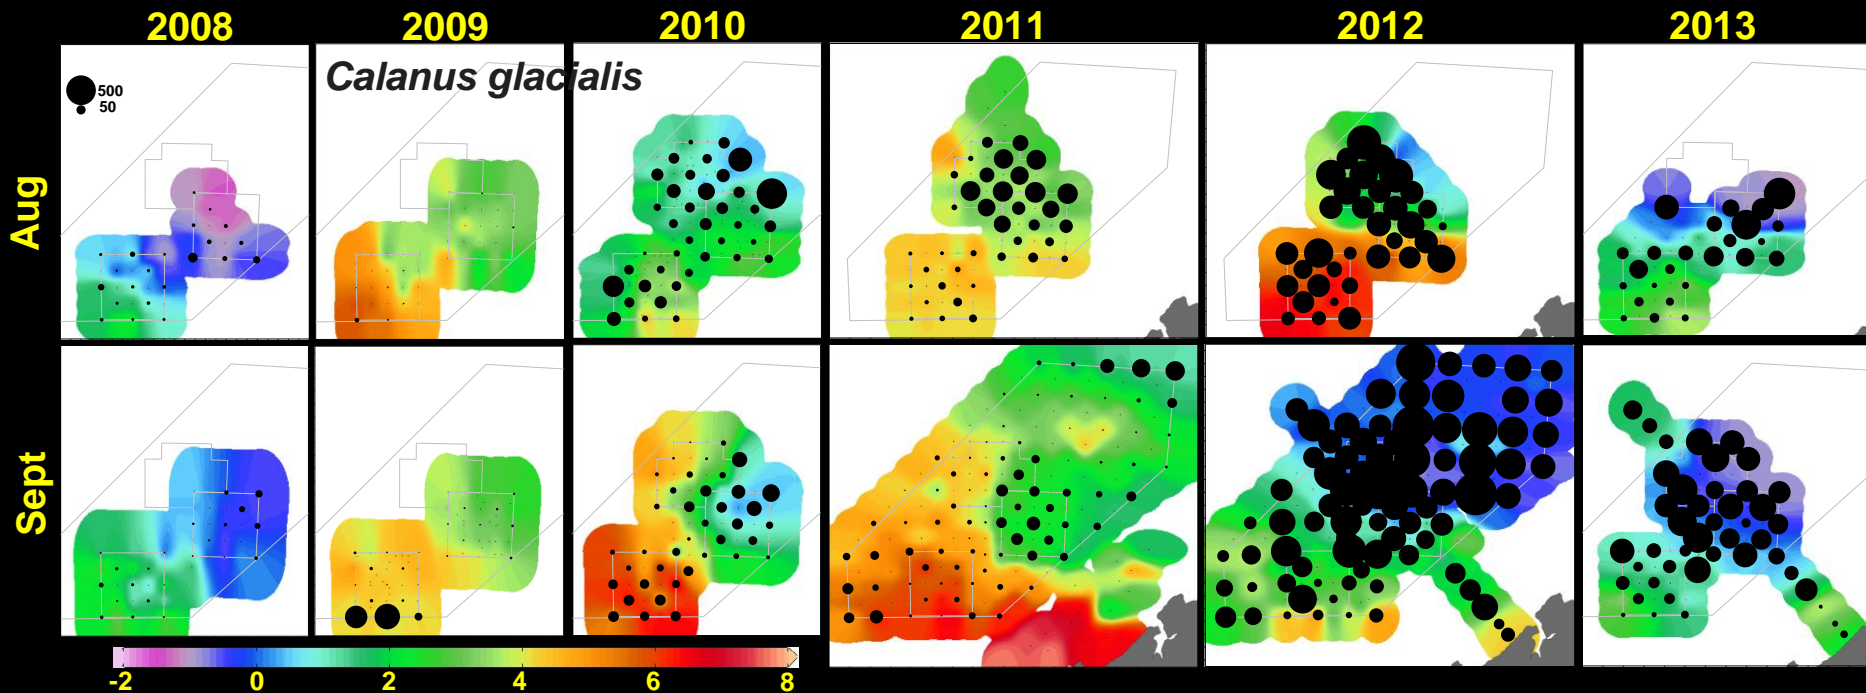

# Chukchi & Beaufort Shelves

- Cross shelf & along-shelf patterns in Beaufort, with distinct communities from Mackenzie River
- Temperature & salinity explain up to 50% within-study

Caveat: interannual difference can be large, but needs to be less than regional differences e.g. the northeastern Chukchi

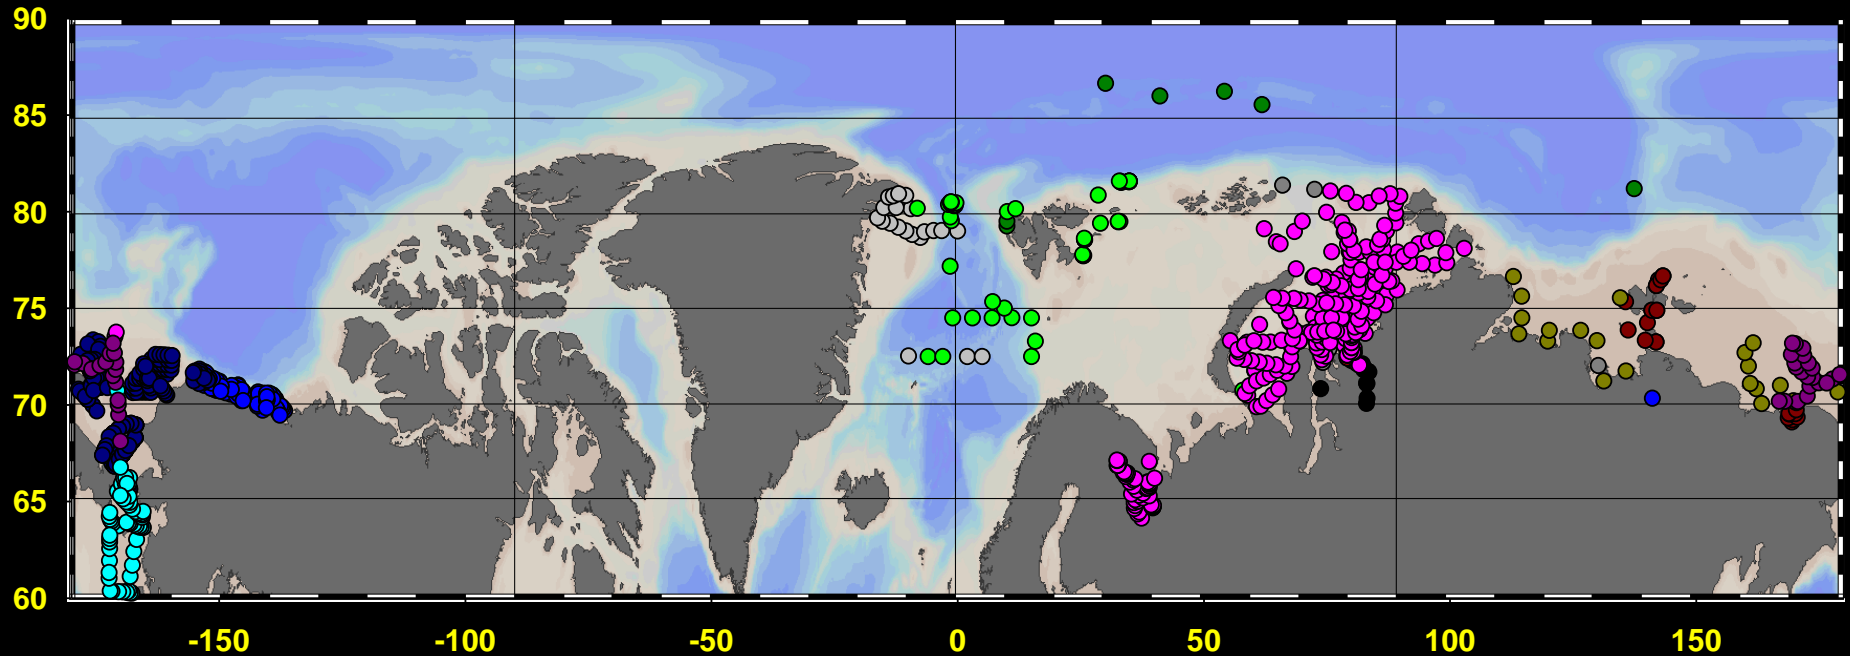

# The Consolidation Challenge

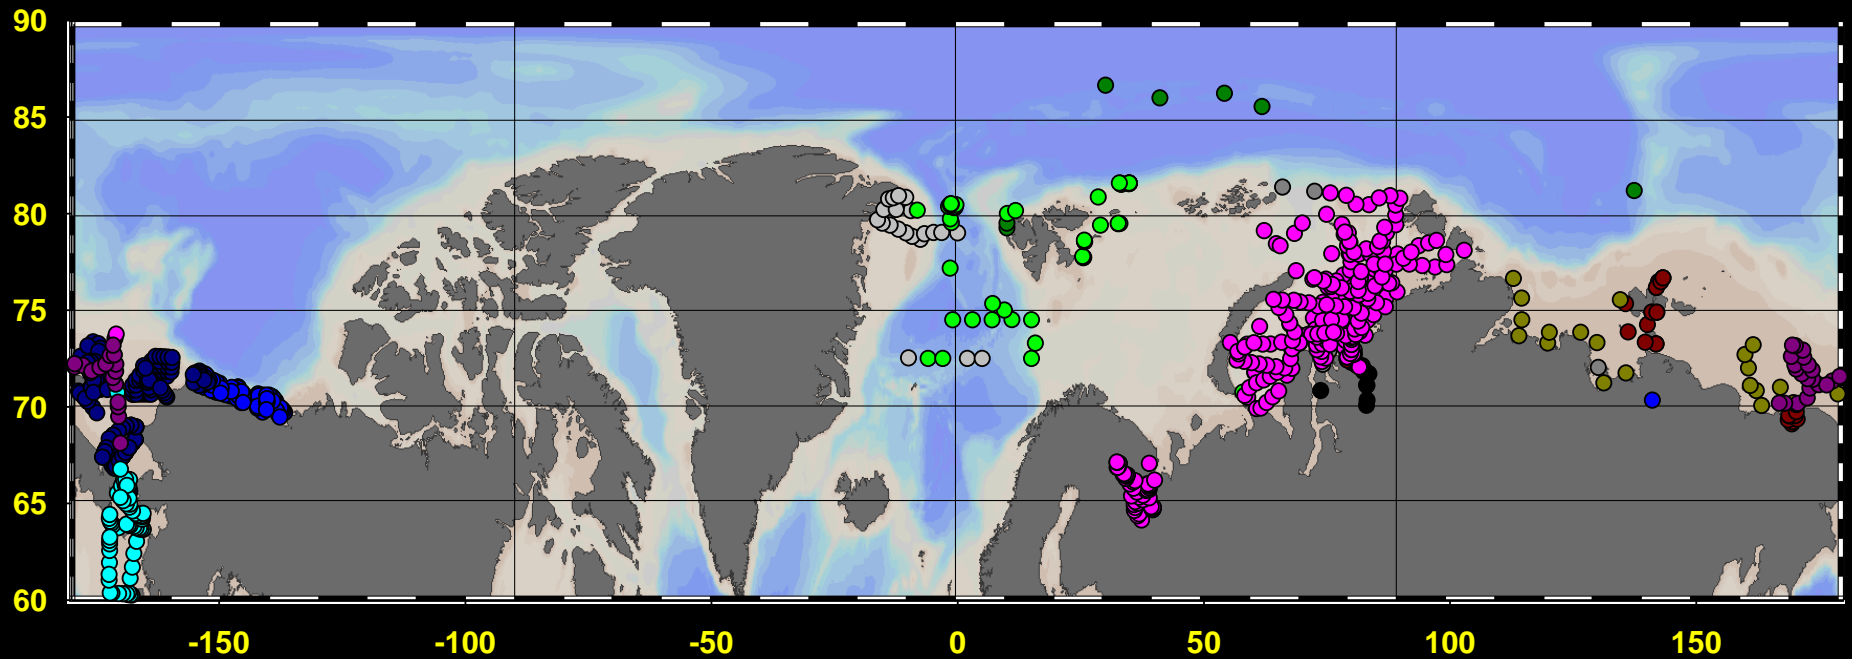

- Collection gear is not standardized (mesh size)
- Taxonomic resolution and SKILL are variable (plus taxonomy itself has changed)
- Few long-term consistently sampled locations (improvement since ~2000)
- Most published works do not include raw data for reanalysis
- General reluctance to share
- ~925 samples for analysis (150-180  $\mu\text{m}$  mesh) from 1930-2014

# First cut at a pan-arctic shelf analysis

- ***Clusters at 35% similarity suggest major differences between regions?***

- Although we can't rule out differences do exist....
- most clusters are heavily confounded by the source of the data (most scientist work regionally)
- Different data sets have different 'quality'
- Collections are seldom archived for re-analysis

Change often happens by shuffling sibling species, so a lack of taxonomic detail (or latter reduction) has major consequences for defining regions and detecting regions and change

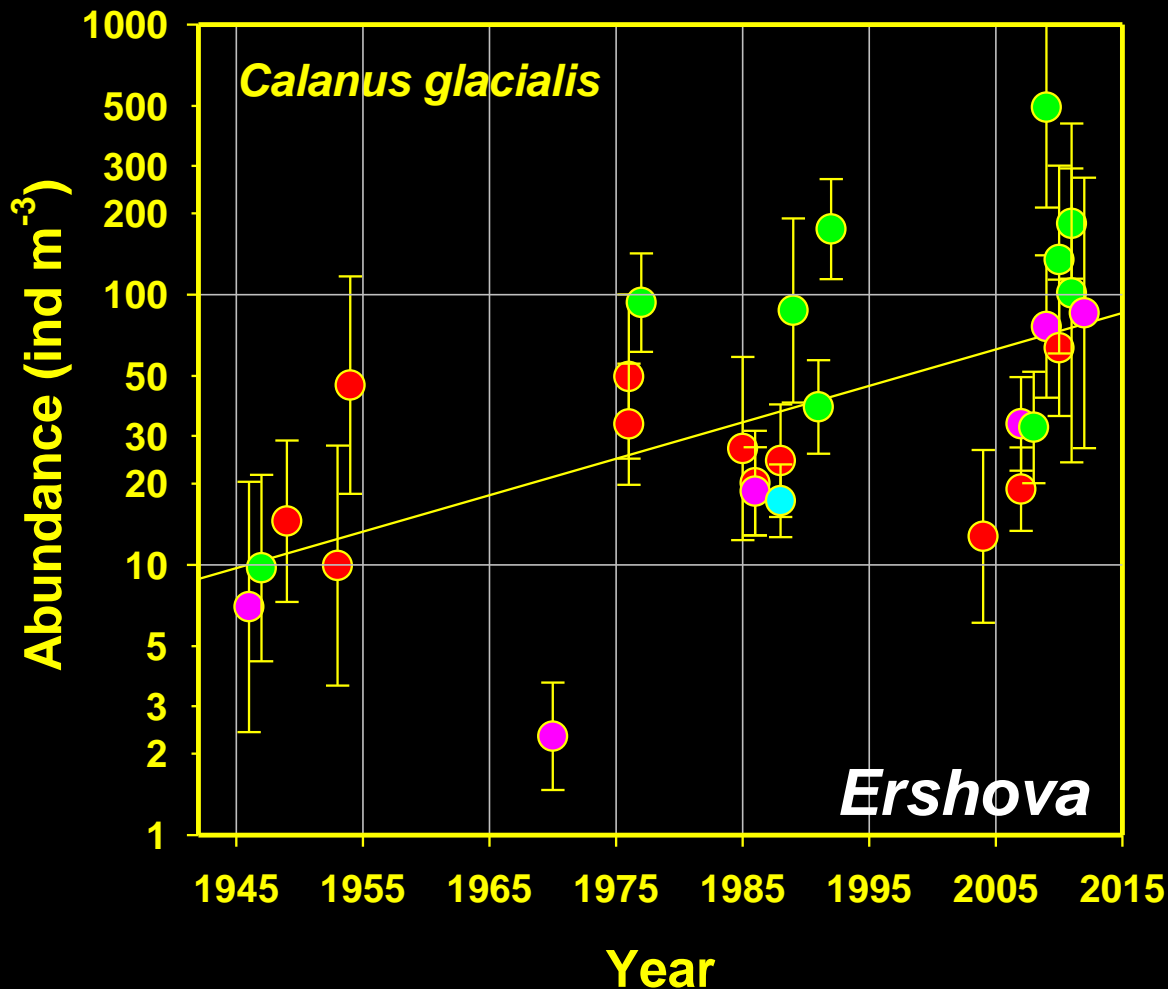

- We are trying to use older data for purposes it was never intended
- Fiddling with data ongoing >> improvement?

- To establish pattern and detect change, we need consistent methodology....
- .... and a long-term commitment to regular observations and time-series

**However, all is not lost.** On a species-by-species basis, it is possible to show systematic changes over time in regional historical data

Iceland & Norway  
~1960, but species-  
level begins 1990

Greenland Fjords  
late 1990s

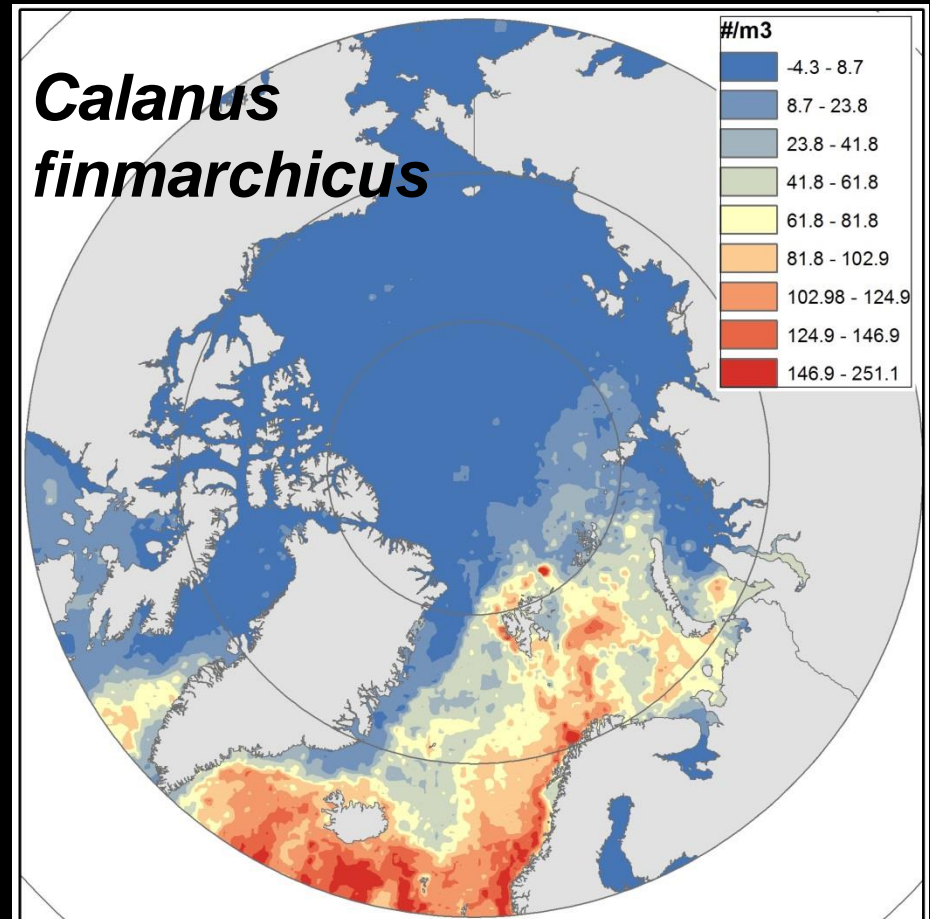

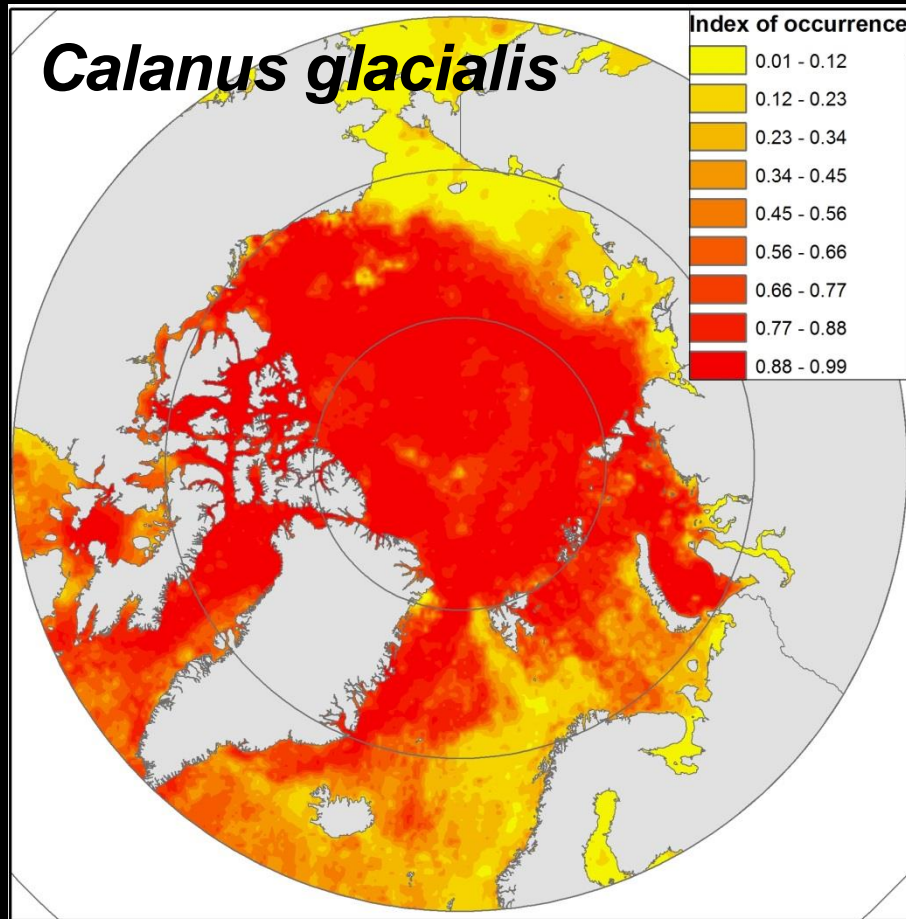

Svalbard Fjords

Faroe Islands

Canada Basin &  
Beaufort Sea (*in  
progress*)

# GIS-based approaches to predicting contemporary species “niche” occurrence & abundance ..... and predicting future based on climate models
